

STATEMENT OF THE PROBLEM

In contemporary business operations, web-based systems have become essential tools for improving efficiency, accuracy, and customer service. These systems minimize the burden of manual data entry and provide organized management of information, thereby reducing errors and delays. As businesses expand, challenges such as handling large volumes of sales data, maintaining consistency of records, and delivering timely services become increasingly evident. Without technological support, these issues hinder operational effectiveness and customer satisfaction.

VA Industrial Electrical Services currently relies on manual processes for inventory management and service coordination. This reliance has led to several operational inefficiencies that may hinder growth and quality services. Specifically, the following problems have been identified:

1. Manual product selection and service form completion: Customers are required to contact the business through social media or email, which is time-consuming and inconvenient.
2. Appointment scheduling through informal messaging: This practice often results in mismanagement of customer queues, delays in responses, and difficulty accommodating high demand.
3. Inventory overstocking and record discrepancies: Manual tallying of tools frequently leads to inconsistencies between recorded data and actual stock counts.

These challenges highlight the need for a web-based inventory and servicing system tailored to VA Industrial Electrical Services. The proposed system aims to streamline product selection, formalize appointment scheduling, and ensure accurate inventory tracking, thereby enhancing overall operational efficiency and customer satisfaction.
